AVL Trees

Chapter 13 CLRS book

Overview

- Review Binary Search Trees
- The Importance of a balanced tree
- AVL Tree
 - It is one kind of balanced tree
 - definition
 - rotations, insertion

BST review

- Each node x has:
 - $\text{key}[x]$
 - Pointers: $\text{left}[x]$, $\text{right}[x]$, $p[x]$
- Property: for any node x :
 - For all nodes y in the **left** subtree of x :
 $\text{key}[y] \leq \text{key}[x]$
 - For all nodes y in the **right** subtree of x :
 $\text{key}[y] \geq \text{key}[x]$

Tree height = 3

BST for runway reservation system

- $R = (37, 41, 46, 49, 56)$ current landing times

- remove t from the set when a plane lands
 $R = (41, 46, 49, 56)$

- add new t to the set if no other landings are scheduled within < 3 minutes from t
 - 40 \Rightarrow reject (41 in R)
 - 42 \Rightarrow reject (41 in R)
 - 53 \Rightarrow ok
- delete, insert take $O(h)$, h =height of the tree

The importance of being balanced

for n nodes:

Perfectly Balanced

$$h = \Theta(\log n)$$

vs.

Path

$$h = \Theta(n)$$

Balanced BST strategy

- Augment every node with some **property**
- Define a **invariant** on the property
- Show that the invariant guarantees $\Theta(\log n)$ height
- Design algorithms to maintain the property and the invariant

AVL Trees: Definition

[Adelson-Velskii and Landis'62]

- **Property:** for every node, store its own height (“augmentation”)

- Leaves have height 0
- NIL has “height” -1

- **Invariant:** for every node x , the heights of its left child and right child differ by at most 1

Now the proof....
AVL Tree's height is $\Theta(\log n)$

AVL trees have height $\Theta(\log n)$

- Let \underline{n}_h be the minimum number of nodes of an AVL tree of height h
- We have

$$\begin{aligned}\underline{n}_h &\geq 1 + \underline{n}_{h-1} + \underline{n}_{h-2} \\ &> 2\underline{n}_{h-2} > 2 \cdot 2\underline{n}_{h-4} > \dots \\ &> 2^{h/2}\end{aligned}$$

$$\Leftrightarrow h < 2\log \underline{n}_h \leq 2\log n$$

$$\Leftrightarrow h = O(\log n)$$

Why $h = \Omega(\log n)$?

- Let m_h be the max number of nodes of an AVL tree of height h
- $m_h \leq 2^h$
- $\log(m_h) \leq h$

Exercise

Question

A) Which of the following AVL trees are balanced?

Insertions/Deletions

- Insert new node u as in the simple BST
 - Can create imbalance
- Similar issue/solution when deleting a node

Balancing

- Let x be the lowest “violating” node (we will try to correct that)
- Assume that x is “right-heavy” (hence we analyze more the right subtree of x)
 - y = right child of x
- Scenarios:
 - Case 1: y is right-heavy
 - Case 2: y is balanced
 - Case 3: y is left-heavy

Case 1: y is right-heavy

Case 2: y is balanced

Same as Case 1

Case 3: y is left-heavy

Need to do more ...

Case 3: y is left-heavy

And we are done!

Examples of insert/balancing

Examples of insert/balancing

Examples of insert/balancing

Examples of insert/balancing

Examples of insert/balancing

Conclusions

- In balanced BSTs all operations take $O(\log n)$ time
- Can **maintain** balanced BSTs using $O(\log n)$ time per insertion

Exercise

- Let's look at AVL tree exercise.ppt
